

1 ABSTRACT OF THE DISCLOSURE

2 A method and apparatus for displaying images are addressed to displaying
3 differing images to the right and left eyes of a user. A right image is presented to the
4 user's right eye by a right display, and a left image is presented to the user's left eye by a
5 left display. When the user's brain processes the right and left images, it performs
6 binocular summation on the two images, and perceives a composite image containing
7 more information than either of the right and left images.
